MODEL — NOT TRACTION

One product engine. Many local brands. One verifiable upside.

A meeting-first social platform deployed by independent operators—measured by privacy-safe telemetry and linked to exit rights through a claim registry.

BUILT

Meeting-first product

Affinity matching, groups, chats, events, resources and feedback.

BUILT

Packaged self-hosting

An installable Debian artifact runs the production stack on the operator's VPS.

PLANNED

Claim registry

Every deployment reports aggregates; a claimed code links weight to an exit-eligible operator.

PROPOSED

Shared success pool

100k founder units; at 1M total units, 10% founder / 90% operator pool.

THE THESIS

Local brands acquire communities. A common core makes verified reach more valuable together than apart—and registry claims allocate that compounding exit upside.

100k / 1M / 10M are economic milestones, not current users

BUILT

The product closes the gap between matching and meeting.

Preference signal > affinity graph > optimized group > real-world event > feedback > better graph.

01 — Preference, not a swipe
Rate people or pairs 1–10; reciprocal and contextual signals feed affinity.

02 — Groups, not only pairs
Graph planning forms balanced rooms and supports inside/outside-network discovery.

03 — Meetings, not endless chat
Scoped chat flows into hosted, multi-stage and tournament-style events.

04 — Operations, not a shell
Invites, assets, tickets, pricing, feedback, moderation and admin tooling.

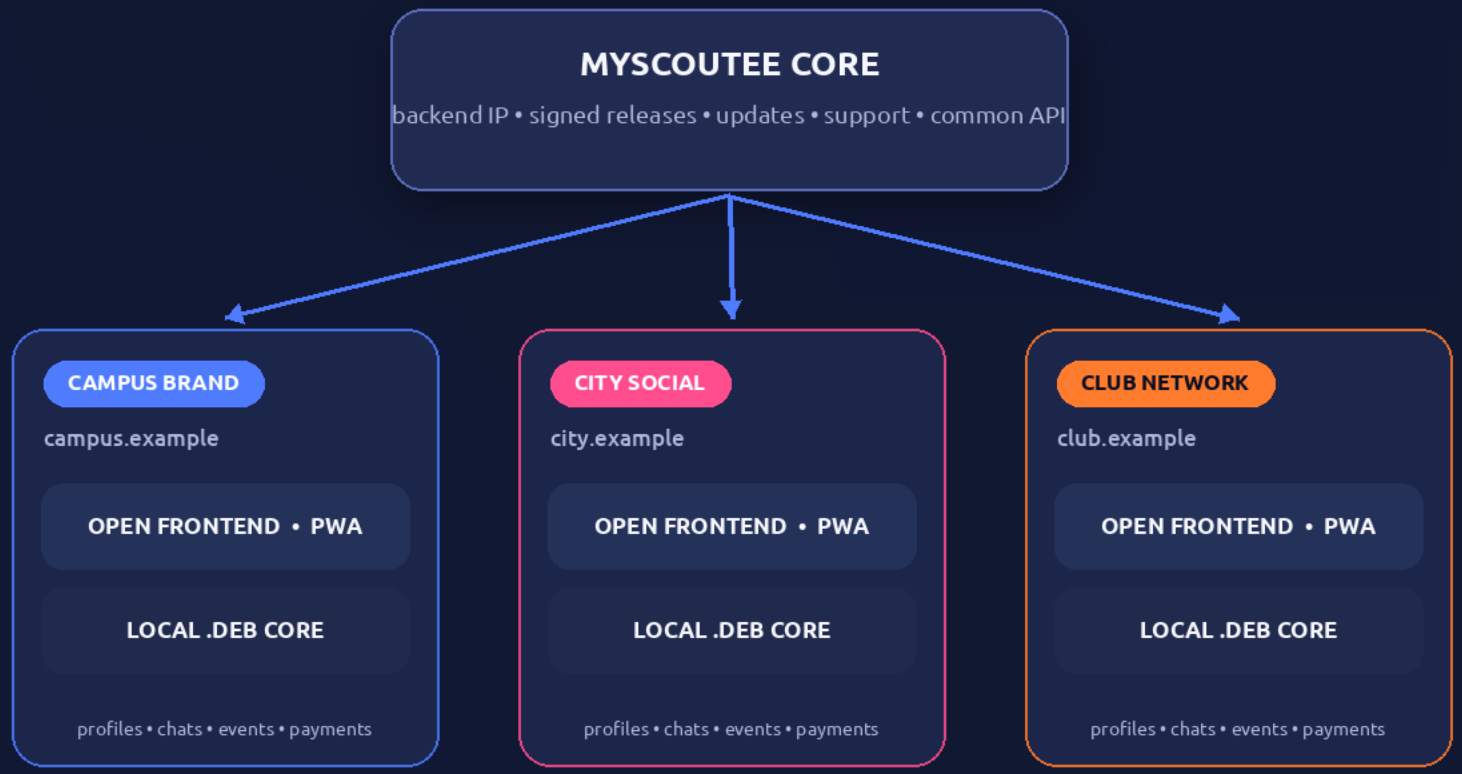

CODEBASE EVIDENCE + CURRENT CAPACITY BOUNDARY • NOT CUSTOMER TRACTION

22	162	51	225/s	10k max
REST controllers	HTTP endpoint mappings	product help explainers	event-read requests	chat connections / deployment
current Java code	current Java code	editable SVG guides	32 VUs • 0% errors • local	current stated ceiling • validate externally

Open distribution surface. Licensed, packaged core.

Operators keep their brand, customer relationship, hosting and local data; MyScoutee standardizes the engine and release rail.

COMMON CORE / LOCAL CONTROL

Aggregate telemetry reports automatically; exit participation begins when the operator claims its deployment code.

BUILT

Deployable artifact exists

`myscoutee_1.0.0_amd64.deb`

193,096,630 bytes • systemd + Docker stack

OPERATOR KEEPS

- Brand, domain and customer/community relationship
- Hosting, local data and operational control
- Own merchant/payment account, pricing and proceeds
- Partners, refunds, tax and commercial responsibility

NETWORK STANDARDIZES

- Compatible signed core and update channel
- Matching, event and resource operating model
- Contribution schema and audit rules (planned)

TRUTH LINE Software executes the payment flow; the operator owns the account and funds.

PLANNED

Every deployment is measured. Only claimed weight participates.

Automatic aggregate telemetry proves scale; a deployment code binds measured history to a verified operator and exit rights.

DEPLOYMENTS > AGGREGATE TELEMETRY > CLAIM REGISTRY

CAMPUS

50k QMAU

signed aggregate + deploy code

CITY

30k QMAU

signed aggregate + deploy code

CLUB

20k QMAU

signed aggregate + deploy code

PLANNED

CLAIM REGISTRY

telemetry measures • code claim attributes

```
verified network MAU
deployment code + status
registered operator
claimed eligible weight
indicative exit share
history + audit
```

NO RAW USER CONTENT

CLAIM CODE

named operator • traceable • exit-eligible

LEAVE UNCLAIMED

telemetry remains • no beneficiary • no exit share

V1 CONTRACT METRIC

Qualified MAU

A distinct human completing at least two substantive actions on at least two days in a rolling 30-day period.

- Substantive = rate, join, message, host, book or verified attendance
- Exclude bots, demos, test accounts, admins and fraud
- One person contributes at most one network unit per month
- Average the six complete months before the measurement date

```
operator weight
= average(QMAU month -6 … month -1)
```

No exit required • valid claims freeze only if an agreed exit occurs.

PROPOSED

Telemetry sets the curve. Claims divide the pool.

Indicative while the network grows; only verified claims at the exit record date become payable.

FOUNDER SHARE AT THE EXIT RECORD DATE

TOTAL	FOUNDER	OPERATOR POOL
200k	50%	50%
500k	20%	80%
1M	10%	90%
10M	10%	90%

WORKING FORMULA

```
B = 100,000 founder units
A = Σ all deployment weights  •  T = B + A
C = Σ claimed operator weights
F = max(10%, B / T)
operator_i = (1 - F) × claimed_i / C
```

AT 1M+ TOTAL UNITS

10% | 90% OPERATOR POOL

EXAMPLE

At 1M+, an operator with 12% of claimed eligible weight receives 10.8% of defined net exit proceeds.

TERM TO LOCK BEFORE EXTERNAL USE

Unclaimed deployment payout = 0. Recommended: it proves scale but does not dilute valid claims. Confirm contractually.

Legal structure required: participation agreement / settlement vehicle, exit definition, net proceeds, record date, audit, fraud clawback, tax and investor priority.

MODEL — NOT TRACTION

At 10M MAU, the fallback is a 5% network commission.

Each deployment handles its own payment flow; operators stay independent and the founder only receives the agreed commission.

PROPOSED

THE TRIGGER

01 — VERIFIED NETWORK REACH
The combined network reaches 10M verified MAU.

↓

02 — NO DEFINED EXIT
No qualifying sale or other agreed liquidity event has occurred.

↓

03 — FALLBACK ACTIVATES
The founder receives a recurring 5% network commission.

NO REVENUE FORECAST HERE

The operator—not the founder—owns the business, customer funds and commercial decisions.

WHAT THE RULE MEANS

Operator autonomy

- Local MyScoutee software handles checkout and payment workflow
- Each operator connects and controls its own payment account
- Customer funds never pass through the founder
- Operator owns pricing, partners, refunds, tax and customer relationship

ECONOMIC RESULT

`founder commission_i = 5% × defined monetization base_i`

COMMISSION — NOT PAYMENT CONTROL

Software can calculate/report the defined 5% base; the operator remains the independent merchant.

Install freely. Claim optionally. Let verified scale compound.

No application or founding cohort: registration only activates identity and economic participation.

SELF-SERVE PARTICIPATION

01 **INSTALL**
Run the packaged .deb under any brand—without applying, registering or naming the operator.

02 **MEASURE**
Automatic aggregate telemetry starts under the unique deployment code issued at deployment.

03 **CLAIM — OPTIONAL**
Register the code whenever you want its measured history attributed to a company or operator.

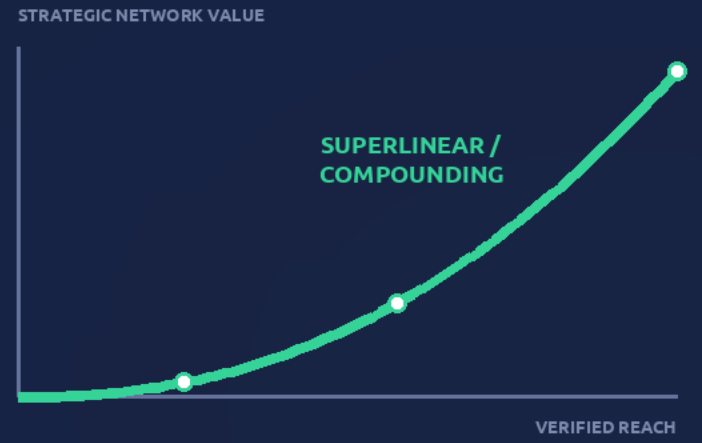

04 **TRACK**
The dashboard shows verified claimed weight and the indicative exit allocation over time.

05 **STAY INDEPENDENT**
Leave it unclaimed: the deployment keeps running, while its exit allocation remains zero.

NO APPLICATION • NO INVITATION • CLAIM WHEN READY

FEDERATED VALUE THESIS

MODEL — NOT VALUATION

```
V(network)  ~  verified_reach ^ alpha
working hypothesis: alpha > 1
```

WHY VALUE CAN COMPOUND

- More local distribution and verified usage
- A larger compatible operating standard
- Greater reach, scarcity and strategic relevance

Value hypothesis—not a guaranteed price curve.
